**ABSTRACT:** In this work, we report that the surface hydroxylation of C<sub>60</sub> molecules is the most likely mechanism for pristine C<sub>60</sub> fullerenes/C<sub>60</sub> fullerene aggregate stabilization in water, being independent of the method of C<sub>60</sub> fullerene aqueous solution preparation.

### INTRODUCTION

Nanocarbon materials are used in a wide variety of biomedical applications, including biosensors, targeted drug delivery, chemotherapy, cellular imaging, and diagnostics.<sup>1</sup> For example, the pristine C<sub>60</sub> fullerenes as a unique class of carbon allotropes are able to penetrate the cell membrane,<sup>2,3</sup> to exhibit antioxidant properties,<sup>4,5</sup> and, being nontoxic (at least at low concentration),<sup>6</sup> to exert specific health effects (e.g., antibacterial,<sup>7</sup> antitumor,<sup>8</sup> and drug carrier<sup>9</sup>).

Biomedical applications require a dispersal of C<sub>60</sub> fullerene in a solvent, with aqueous dispersions being preferred because of biocompatibility, safety, or environmental concerns. Although pristine C<sub>60</sub> fullerenes have extremely low water solubility, they can form stable colloid solutions containing individual C<sub>60</sub> fullerenes as well as C<sub>60</sub> fullerene aggregates (clusters) in water when subjected to extended mixing, sonication, or solvent exchange<sup>10–16</sup> (to be further referred to as a C<sub>60</sub> fullerene aqueous colloid solution (C<sub>60</sub>FAS)). However, the origin of stabilization of such particles in water still remains poorly investigated.

At least two approaches have been suggested in order to explain the stability of fullerene particles in water solutions. One of them<sup>17</sup> postulates the formation of a water shell around C<sub>60</sub> molecules stabilized simultaneously by the H-bonding network between the water molecules and charge transfer from water to the C<sub>60</sub> fullerene. Another one<sup>18</sup> suggests that the sonication process induces the covalent attachment of water hydroxyls to C<sub>60</sub> fullerene carbons, resulting in the formation of alcohol moieties that enable C<sub>60</sub> fullerene dissolution. The

problem here is that the properties of C<sub>60</sub>FAS (including biological properties) as well as the mechanism of water solubility may depend on the method of preparation of C<sub>60</sub> fullerene aqueous solution.<sup>13,16,17</sup> Indeed, these two approaches differ by the underlying method of C<sub>60</sub>FAS preparation although the sonication step is presented in both methods. The question therefore arises as to whether the mechanism of solubility of C<sub>60</sub> fullerene in water depends on the method of C<sub>60</sub>FAS preparation. This question has been investigated in this article.

### EXPERIMENTAL SECTION

**Sample Preparation.** For the preparation of C<sub>60</sub>FAS, we used a saturated solution of pure C<sub>60</sub> fullerene (purity >99.99%) in toluene with a C<sub>60</sub> molecule concentration corresponding to maximum solubility near 2.9 mg/mL and the same amount of distilled water in an open beaker. The two phases that formed were treated in an ultrasonic bath. The procedure was continued until the toluene had completely evaporated and the water phase became yellow. Filtration of the aqueous solution allowed us to separate the product from undissolved C<sub>60</sub> fullerenes. The pore size of the filter during the filtration of the aqueous solution was smaller than 2 μm (Typ Whatmann 602 h1/2).

The purity of the prepared C<sub>60</sub>FAS samples was determined by HPLC and GC/MS techniques using standard protocols. Insoluble impurities in C<sub>60</sub>FAS were determined by ultracentrifugation: it was found that their amount is less than 1 μg/mL. Toluene from the

Received: January 3, 2014

Published: March 24, 2014

synthesis could not be detected in the water by GC/MS analysis. Moreover, the  $^1\text{H}$  NMR spectrum (400 MHz) of  $\text{C}_{60}$ FAS did not reveal any residual proton signals.

The concentration of  $\text{C}_{60}$  fullerene in the prepared  $\text{C}_{60}$ FAS sample was determined as the concentration of total carbon in aqueous solution (Analytik Jena TOC analyzer multi N/C 3100). In our experiments, the  $\text{C}_{60}$ FAS samples with 0.15 and 0.026 (approximately 6 times less) mg/mL concentrations of  $\text{C}_{60}$  fullerene were used.

**Sample AFM Characterization.** The state of  $\text{C}_{60}$  fullerene in water was monitored using atomic force microscopy (AFM, Solver Pro M system, NT-MDT, Russia). In the AFM study, the samples were deposited by precipitation from an aqueous solution droplet onto a cleaved mica substrate (V-1 grade, SPI Supplies). The sample visualization in the AFM experiments was carried out in a semicontact (tapping) mode using NSG10 (NT-MDT) probes.

**Sample SANS Characterization.** Small-angle neutron scattering (SANS) measurements were carried out at the YuMO small-angle diffractometer at the IBR-2 pulsed reactor (JINR, Dubna, Russia) in the time-of-flight regime. On the YuMO small-angle spectrometer, the two-detector setup with ring wire detectors was used.<sup>19</sup> The neutron wavelength range was 0.05–0.8 nm. The measured scattering curves were corrected for background scattering from buffer solutions. For an absolute calibration of the scattering intensity during the measurements, a vanadium standard was used. Treatment of the raw data was performed by the SAS program with a smoothing mode enabled.<sup>20</sup>

**Sample FTIR Characterization.** Fourier transform infrared (FTIR) spectroscopy was used to study the structural organization of pristine  $\text{C}_{60}$  fullerenes in water (0.15 mg/mL). The FTIR spectrum was recorded using a Perkin-Elmer BX-II spectrophotometer with a spectral resolution of  $1\text{ cm}^{-1}$  in the range of  $4000\text{--}400\text{ cm}^{-1}$ . A  $\text{C}_{60}$ FAS sample was examined directly as a thin film placed between two NaBr plates by the liquid membrane method. The sample (for comparison) consisting of 20%  $\text{C}_{60}$  fullerene powder and 80% KBr was compressed (150 kgF) into a tablet with a size of  $15 \times 15 \times 0.1\text{ mm}^3$ .

## RESULTS AND DISCUSSION

In this work, we aimed to ascertain whether the mechanism of aqueous solubility of  $\text{C}_{60}$  fullerene particles may depend on the method of  $\text{C}_{60}$ FAS preparation. Two representative methods of stable  $\text{C}_{60}$ FAS preparation have been selected, which have so far been the most well characterized in terms of the morphological properties of the resultant fullerene solution and the mechanism of fullerene aqueous solubility.

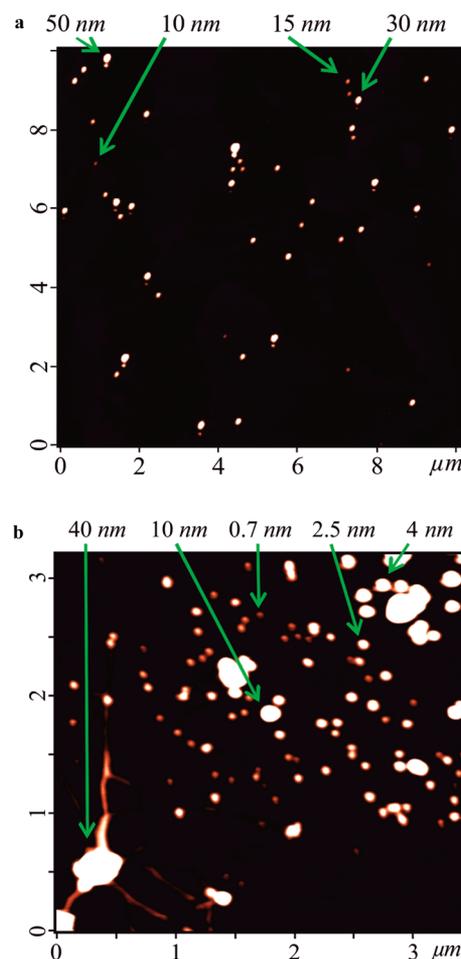

Method 1<sup>18,21</sup> is based on prolonged mixing of the  $\text{C}_{60}$  fullerene powder and water with ultrasonic processing of the mixture and belongs to the group of methods that use extended mixing in water. It has been reported<sup>18</sup> that the aqueous solubility of  $\text{C}_{60}$  fullerene prepared by this method is a consequence of the formation of C–OH groups on the surface of  $\text{C}_{60}$  molecules, which facilitates the dissolution.

Method 2<sup>12,13,21</sup> is based on the technology of transferring  $\text{C}_{60}$  fullerenes from toluene (or other organic solvents) to an aqueous phase with the help of ultrasonic treatment and belongs to the group of solvent-exchange methods of  $\text{C}_{60}$ FAS preparation. It has been reported<sup>17</sup> that the aqueous solubility of  $\text{C}_{60}$  fullerene prepared by this method is a consequence of the formation of a stable water shell around fullerene molecules resulting from the H-bonding network and charge transfer from water to fullerene.

We used method 2 to determine whether the formation of C–OH groups may also occur during  $\text{C}_{60}$ FAS preparation. The first necessary step in such an analysis is the structural characterization of the prepared  $\text{C}_{60}$  fullerene solution.

**Characterization of  $\text{C}_{60}$ FAS.** To characterize the composition of the prepared  $\text{C}_{60}$ FAS, AFM and SANS measurements were performed.

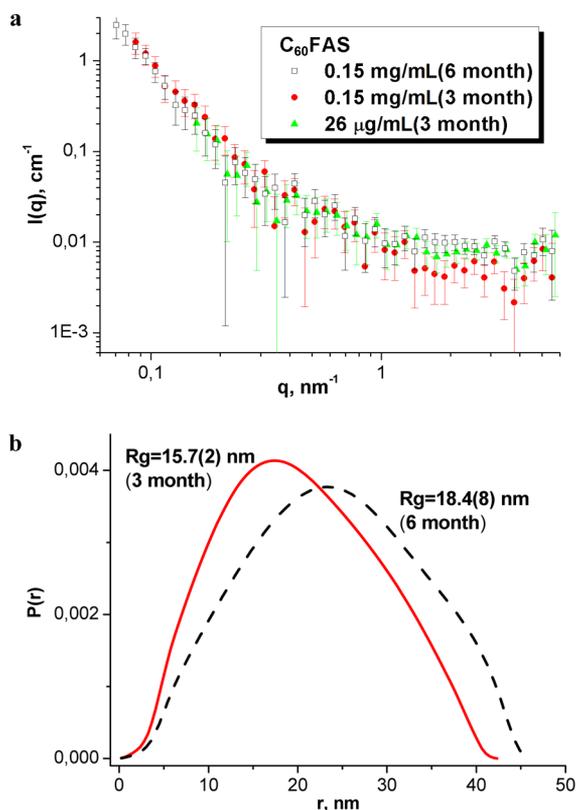

The AFM picture in Figure 1 corresponds to various concentrations of  $\text{C}_{60}$  fullerene in water, viz. 0.15 (Figure 1a)

**Figure 1.** AFM images of  $\text{C}_{60}$  fullerenes on the mica surface, which were precipitated from the  $\text{C}_{60}$ FAS system at 0.15 (a) and 0.026 (b) mg/mL concentrations (3 months after preparation).

and 0.026 (Figure 1b) mg/mL. It demonstrates randomly arranged individual  $\text{C}_{60}$  molecules with a diameter  $\sim 0.7$  nm and their bulk spherulike aggregates with a height of 2–50 nm.

The experimental SANS curves for the  $\text{C}_{60}$ FAS system at two  $\text{C}_{60}$  fullerene concentrations (0.15 and 0.026 mg/mL) are presented in Figure 2a. The absence of specific peculiarities on the curves suggests that the particles are polydisperse in size. It should be noted that a 0.026 mg/mL concentration of  $\text{C}_{60}$  fullerene is the minimum value at which the SANS signal can be detected. (The signal is close to the background level.) One can see similar SANS curves in the case of a 0.15 mg/mL concentration of  $\text{C}_{60}$  fullerene after 3 and 6 months of preparation, which points out similar aggregate structures in both solutions. The experimental SANS curves were processed by indirect Fourier transform according to ref 20. The satisfactory fit was obtained only for a 0.15 mg/mL concentration of  $\text{C}_{60}$  fullerene in the  $\text{C}_{60}$ FAS system. The pair distance distribution,  $P(r)$ , inside  $\text{C}_{60}$  fullerene aggregates, obtained using spherically symmetric basis functions, is shown in Figure 2b. The resulting values of the radius of gyration,  $R_g = 18.4 \pm 0.8$  nm (after 6 months of preparation) and  $R_g = 15.7 \pm 0.2$  nm (after 3 months of preparation), correspond to the radius for homogeneous spheres equal to 20 nm and are in

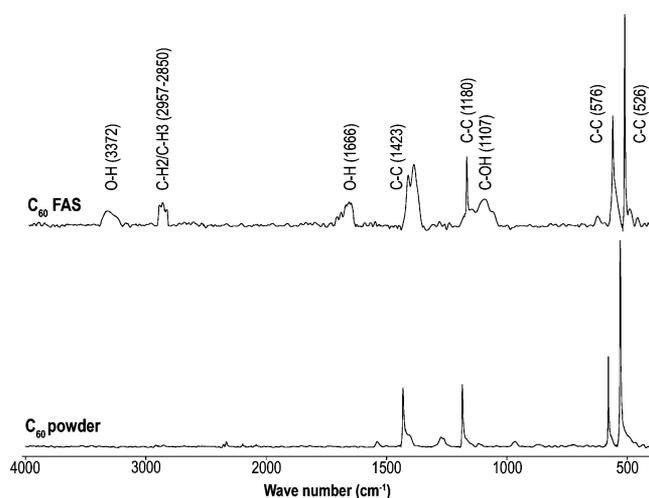

**Figure 2.** SANS curves (a) for  $C_{60}$ FAS systems at 0.15 (squares, 3 months after preparation; and circles, 3 months after preparation) and 0.026 (triangles, 3 months after preparation) mg/mL concentrations of  $C_{60}$  fullerene; the obtained pair distance distribution,  $P(r)$ , (b) for  $C_{60}$  fullerene clusters in solution at a 0.15 mg/mL concentration (solid line, 3 months after preparation; and dashed line, 6 months after preparation).

agreement with the aggregate sizes, as seen via AFM (Figure 1a). The measured sizes are slightly smaller than those reported previously<sup>22</sup> using essentially the same method of  $C_{60}$ FAS preparation by toluene extraction, which may be associated with different concentrations and/or minor differences in the protocols of preparation employed, as noted before.<sup>23</sup> At the same time, the main morphological and spectroscopic properties of our  $C_{60}$ FAS<sup>11,23</sup> are in good agreement with data reported by other authors.<sup>16,21,24</sup>

In summary, the SANS and AFM data indicate that polydisperse  $C_{60}$  fullerene aggregates (0.7–90 nm in size) present in the  $C_{60}$ FAS system and the prepared fullerene aqueous solution remain stable for quite a long time. These features appear to be similar for different methods of  $C_{60}$ FAS preparation.

**Origin of  $C_{60}$  Fullerene Solubility in Water.** To clarify the possible mechanism of  $C_{60}$  fullerene hydrophilic character after exposure to water, the FTIR measurements were performed.

The FTIR spectrum of  $C_{60}$ FAS (0.15 mg/mL) is shown in Figure 3 together with the reference spectrum of pristine  $C_{60}$  fullerene powder. The spectra display four intense peaks at 1423, 1180, 576, and 526  $\text{cm}^{-1}$  attributed to C–C vibrational modes of the  $C_{60}$  molecule.<sup>25</sup> For the  $C_{60}$ FAS system, however, additional peaks are observed: the bands at 3372 and 1666  $\text{cm}^{-1}$  correspond to O–H stretching and bending, respectively. But the most interesting feature of the FTIR spectrum of

**Figure 3.** Comparison in the FTIR spectra of the  $C_{60}$ FAS system (0.15 mg/mL) and the original pristine  $C_{60}$  fullerene powder.

$C_{60}$ FAS is the broad, intense band near 1107  $\text{cm}^{-1}$  attributed to C–OH stretching.<sup>26</sup> The FTIR spectrum of  $C_{60}$ FAS is also characterized by the C–H stretching bands at 2957–2850  $\text{cm}^{-1}$ , which are obviously absent in pristine  $C_{60}$  fullerene powder. Given the composition of the  $C_{60}$ FAS system, the observed C–O vibrations strongly suggest that the  $C_{60}$  fullerene cage is hydroxylated and hydroxyls forming alcohol functional groups exist in the structure of  $C_{60}$ FAS.

The hydroxylation of the fullerene cage found in the present work for  $C_{60}$ FAS prepared by method 2 is in agreement with the same experimental evidence reported in ref 18 by FTIR for  $C_{60}$ FAS prepared by method 1. It strongly suggests that the primary mechanism of  $C_{60}$  fullerene solubilization in water is the attachment of the OH groups to  $C_{60}$  fullerene carbons, which explains why the lone  $C_{60}$  molecules and their clusters exist at equilibrium in solution for quite a long time (see above), a feature that is independent of the method of  $C_{60}$ FAS preparation. It also explains the irreversible character of the adsorption/desorption isotherms reported earlier,<sup>27</sup> the minimal extraction of  $C_{60}$  fullerene from water–colloid solutions by toluene,<sup>28</sup> and the ability of  $C_{60}$  fullerenes from  $C_{60}$ FAS to hold water molecules even in vacuum.<sup>17</sup> The covalent attachment of the OH groups does not exclude the possibility of electron transfer from water molecules to  $C_{60}$  fullerene, enabling us to explain the negative charge on fullerene particles.<sup>17,18,28</sup> However, the previous model of stabilization of hydrated  $C_{60}$  fullerene by water molecules joined together by an H-bonding network<sup>17,23</sup> needs to be corrected in view of the available results of molecular dynamics simulations of hydrated  $C_{60}$  fullerenes<sup>29,30</sup> reporting the weakening and breakage of the H bonds between water molecules in the immediate vicinity of the  $C_{60}$  fullerene surface as a result of the overbalancing effect of  $C_{60}$  fullerene–water with respect to the water–water interaction.

## CONCLUSIONS

It may be concluded that the surface hydroxylation of  $C_{60}$  molecules is the most likely mechanism for pristine  $C_{60}$  fullerenes/ $C_{60}$  fullerene aggregates stabilization in water, being independent of the method of  $C_{60}$ FAS preparation. The general importance of hydroxyls in the state of  $C_{60}$  fullerenes in water has been noted by numerous workers in

the past<sup>17,21,31</sup> for different methods of fullerene aqueous solution preparation, although the exact role played by hydroxyls in the stabilization of C<sub>60</sub>FAS has so far been unclear. The covalent attachment, revealed in the present work, gives deeper insight into this problem. However, further studies are required in order to clarify the mechanism by which this attachment occurs.
